Simplified Open-window Technique for a Horizontally Impacted Maxillary Canine with a Dilacerated Root

Introduction
A left maxillary canine with a dilacerated root is horizontally impacted in the palate. Extraction is undesirable, so the preferred option is efficient surgical exposure and orthodontic alignment.\(^1\) For palatal impactions, the open window technique is a common surgical approach.\(^2,3\) There are multiple surgical and orthodontic options to customize the process for a specific patient.\(^4,6\) This article illustrates the step-by-step surgical procedures as a checklist to assist clinicians in efficiently recovering palatally-impacted maxillary canines.

Case Study
A 12 year 8 month old boy presented for assessment of an unerupted maxillary canine. A panoramic radiograph (Fig. 1) showed an impacted upper left canine associated with a retained deciduous canine on the same side. Intraoral occlusal photographs (Figs. 2 and 3) show modest alignment problems as well as caries in the retained maxillary canine. Three-dimensional (3D) renderings of a cone-beam computed tomography (CBCT) scan\(^7\) showed that the crown of the impacted canine was oriented distally, near the apices of the

adjacent premolars (Figs. 4 and 5). CBCT slices along the long axis of the tooth, and perpendicular to it, revealed the impaction was completely covered with bone (Figs. 6 and 7). A periapical film demonstrated root dilaceration of the impacted canine, and incomplete apical development (Fig. 8). Radiographic documentation (Figs. 1 and 4-8) provides the precise location of the impacted tooth prior to surgery to uncovering it. The specialized procedures for surgically exposing this challenging impaction are presented in a checklist.
Surgery Procedures

1. Orientation

- Locate the position of the impacted canine.

  » Plane radiographs (occlusal and periapical films) may be adequate for localizing and determining the root shape of relatively simple soft tissue impactions, but bony impactions require CBCT imaging for precise localization relative to adjacent teeth (Fig. 9). Slices from the CBCT
Imaging are also useful for determining the thickness and density of the bone covering the tooth (Fig. 6). In addition, 3D imaging reveals the root shape (Fig. 7), and any anomalies present that may limit the prognosis for the impaction, even if it is aligned. This is an important aspect of differential diagnosis. It is a waste of time and money to recover an unserviceable tooth.

2. Indentation

- **Apply local anesthesia to the surgical site.**
- **Mark the location of the crown with a sharp explorer.**

The sensation is different when an explorer strikes a tooth rather than bone. Enamel is very rigid and there is no penetration by even a sharp stainless steel (SS) explorer. A tooth root is not as hard as the enamel, but penetration by the explorer tip is quite limited. The explorer will penetrate bone with a crunchy sensation.

3. Flap Reflection

- **Incise the soft tissue along the long axis of the crown with a No. 15c surgical scalpel (Fig. 11).**
- **Reflect the flap with a surgical curette or periosteal elevator.**
- **Beware of the greater palatine artery (Fig. 11) which courses through the center of each half of the palate. If possible make incisions parallel to the artery and avoid deep transverse sections that may sever it.**

The soft tissue covering the crown of the impacted canine is removed with electrosurgery.
Use a dental electrosurgical unit (ESU) to remove the soft tissue covering the crown (Fig. 12). ESU controls localized bleeding by cauterizing vessels and coagulating blood. This method prevents blood oozing from the wound, thereby providing good visualization of the surgical field.

Use an explorer to penetrate overlying bone to determine the position of the cuspid crown (Fig. 13).

Differential sensations when an explorer engages enamel, the root of the tooth or bone is a very effective method for surgically locating the crown of the impaction.

4. Bone Removal

Use a high speed handpiece with a carbide round bur to remove the overlying bone (Fig. 14).

It is essential to remove all bone covering the crown down to the cementoenamel junction (CEJ). Spontaneous tooth eruption is facilitated by removing bone apical to the height of curvature of the crown. Be cautious with the bur near the CEJ to avoid injuring the tooth. When the layer of overlying bone is thinned sufficiently, the remnant is easily removed with a hand instrument. Cervical damage to the tooth can subsequently result in external root resorption.

The etching solution is applied to the enamel surface with a syringe (upper left). Moisture is controlled with surgical suction (grey tube).
5. Etching & Bonding

- **Etching & Bonding**
  - Moisture control is very important when etching, sealing and bonding. Bleeding is controlled with electrocautery. Water, saliva and residual blood are removed with high power suction (Figs. 15 and 16).

6. Indentation

- **Bond a button on the crown portion of the impacted canine.**
- **Make an indentation in the rugae area where the miniscrew will be inserted.**

7. Screws Insertion

- **A miniscrew is inserted mesial to the impaction.**
- **An elastic power chain is attached from the button on the impaction to the miniscrew.**
  - The miniscrew is placed on the mesial surface to upright the impacted canine with an elastic power chain. This force system provides direct traction to upright the impaction without deleterious side effects on the rest of the dentition. It is often necessary to reposition the miniscrew as the tooth is uprighted. Beware of impinging on the roots of teeth and creating occlusal interferences.  

**Fig. 16:** After the etched surface is rinsed and dried, the sealant is applied with a yellow brush.

**Fig. 17:** After the button was bonded on the crown of the impacted canine, the position for the miniscrew was marked by penetrating the soft tissue in the rugae area with an explorer.

**Fig. 18:** Traction is applied with a power chain to upright the canine, and a coil spring is used to open space in the arch for the impaction.
• Spread petroleum jelly on the back of a glove to coat glove fingers to prevent sticking to the periodontal dressing (COE-PAK).⁴,⁵

8. COE-PAK Application

• Coat glove finger tips with petroleum jelly from the back of the glove (Fig. 19).

• Cover the wound with periodontal dressing and pack it into the interdental spaces and around the miniscrew.

• Use wet gauze or a cotton swab to press the periodontal dressing into firm contact with the wound.
  
  » Packing the dressing into the interdental spaces provides retention.

  » Periodontal dressing controls bleeding, enhances patient comfort, and most importantly prevents the mucosa from growing over the uncovered impaction (open window technique).

  » Healing mucosa grows ~1mm/day which is much faster than a tooth erupts. The dressing is essential for maintaining the patency of the window until the tooth erupts through it.

  » Periodontal dressing is removed three days after the surgery and the eruption of the impaction is closely monitored for ~3 weeks or until it erupts through the mucosa.

• Extract the primary canine (Figs. 20 and 21).

Fig. 19: Petroleum jelly is applied to the back of a glove to assist in manipulating the periodontal dressing.

Fig. 20: Periodontal dressing is covering the wound and the miniscrew, and the carious maxillary left deciduous cuspid is prepared for extraction.

Fig. 21: After extraction the deciduous canine shows both extensive crown and root destruction.
Discussion
For most palatal impactions, the open window approach allows for spontaneous eruption. However, that approach is less likely to be successful for bony impactions, particularly when horizontal, deep in the alveolar process, with a dilacerated root, in an older patient, or when a miniscrew is required.9 Deep bony impactions usually require traction for eruption (Fig. 18). However, the most critical issue in dealing with bony impactions in the posterior palate is avoiding damage to the greater palatine artery (GPA)(Fig. 22),1,2 which is the terminal portion of the descending palatine artery, that is derived from the maxillary artery (Fig. 23). The GPA enters the palatal soft tissue through the greater palatine foramen, and provides the blood supply for the gingiva and mucosa of the posterior palate (Fig. 22). It terminates through the incisive canal by anastomosing with the sphenopalatine artery to supply the nasal septum (Fig. 23). The GPA is a relatively large artery in the posterior palate that is capable of significant bleeding if severed. The surgeon must avoid any incisions that threaten the GPA. If an impaction is near the GPA, it may be best to reflect the soft tissue of the palate to expose the impaction.

Dilaceration is a developmental disturbance in the shape of a tooth, and it may affect both the deciduous and permanent dentitions.9 The term dilaceration refers to a curvature in some aspect of a tooth. It usually involves the cervical region and/
or the root of a tooth. If the problem is genetic, it usually also affects the same tooth on the opposite side of the arch, because the genome contains genes for only half of the body: the other half is a mirror image. Isolated cases of dilaceration are usually due to trauma during tooth development or the tooth being impeded during eruption. Trauma may displace the formed portion of the tooth germ, so that the rest of the tooth forms at an abnormal angle. Eruption is such that the apical area remains at the same place while the crown moves occlusally, but if eruption is mechanically blocked, the proliferating apical area will move into different direction. The ensuing distortion of root form is deemed dilaceration.

### Conclusion

For many years, extraction was the recommended treatment for a dilacerated impactions, but modern technology offers new options. Conservative surgical exposure and bone screw anchorage facilitates the recovery and alignment of even severely displaced impactions. This article provides a step by step sequence (checklist) to assist the clinician in managing palatal impactions in a standardized manner with the open-window technique.
